Amendments to the Claims:

This listing of claims will replace all prior versions, and listings, of claims in the

application:

Listing of Claims:

1. (Previously presented) A method of processing a series of data packets for transmission

over a data network in a series of frames, each data packet in the series of data packets having a

respective time in a time sequence, each frame being capable of transmitting a certain amount of

data, the method comprising:

successively joining data packets from the time sequence into the frames and delaying

transmission of some of the data packets so that at least some of the frames each contain multiple

data packets, and transmitting each data packet in at least one of the frames no later than a

certain time interval after the respective time of said each data packet in the time sequence,

which includes

(a) transmitting each frame in a first set of the frames upon filling said each frame in the

first set of frames with data from one or more of the data packets so that said each frame in the

first set of frames cannot contain an additional data packet; and

(b) upon delaying packet transmission for the certain time interval, transmitting each

frame in a second set of the frames which are not filled with at least some of the data packets so

that said each frame in the second set of the frames cannot contain an additional data packet in

order to ensure that said each data packet is transmitted in at least one of the frames no later than

the certain time interval after the respective time of said each data packet in the time sequence.

(Original) The method as claimed in claim 1, wherein a main routine for processing said

each data packet initiates the transmitting of each frame in the first set of the frames upon filling

said each frame in the first set of frames with data from one or more of the data packets so that

said each frame in the first set of frames cannot contain an additional data packet; and

wherein a timer interrupt routine initiates the transmitting of each frame in the second set

of the frames which are not filled with at least some of the data packets so that said each frame in

the second set of the frames cannot contain an additional data packet in order to ensure that said

each data packet is transmitted in at least one of the frames no later than the certain time interval

after the respective time of said each data packet in the time sequence.

3. (Original) The method as claimed in claim 1, wherein the data packets include read I/O

request data packets and write I/O request data packets, and the method includes separately

joining the read I/O request data packets together for transmission, and separately joining the

write I/O request data packets together for transmission, so that the I/O request data packets have

an ordering in the frames that is different from the ordering of the I/O request data packets in the

time sequence.

4. (Original) The method as claimed in claim 3, wherein some of the read I/O request data

packets are moved in front of some of the write I/O request data packets in some of the frames.

Ser. No. 10/761,767

Amendment in Reply to OA of 03/03/2009

5. (Original) The method of claim 1, wherein the data packets are I/O request data packets,

and the method includes on-line transaction processing applications in a host processor

producing the data packets, and a TCP/IP interface in the host processor transmitting the frames

over an IP network to network attached storage containing a database accessed by the on-line

transaction processing applications.

6. (Original) The method of claim 1, wherein the data packets are I/O replies from network

attached storage, and the frames are transmitted to a host processor accessing the network

attached storage.

7. (Original) The method of claim 1, wherein the data packets are stored in a range of

addresses of memory, a certain number of frames are preallocated in another region of memory,

and the data packets are joined by transfer of the data packets from the range of addresses in

memory to the preallocated frames in memory.

8. (Original) The method of claim 7, wherein the certain number of preallocated frames are

periodically updated.

9. (Original) The method of claim 7, which includes application threads loading the data

packets into the memory at the range of addresses in memory.

Ser. No. 10/761,767

Amendment in Reply to OA of 03/03/2009

10. (Original) The method of claim 7, which includes TCP/IP threads accessing the pool of

preallocated frames for transmission of the preallocated frames including the data packets over

an IP network.

11. (Original) The method as claimed in claim 1, which includes transmitting the frames

over a data network, measuring loading on the data network, and dynamically adjusting the

duration of the certain time interval based on the measured loading of the data network, the

duration of the certain time interval being increased for increased loading on the data network.

Claim 12. (Canceled).

13. (Currently amended) The method as claimed in claim 12. In a host processor

programmed for executing on-line transaction processing applications and having a network

block storage interface for accessing network attached storage coupled to the host processor via a

data network, a method comprising the host processor joining I/O request data packets from

different ones of the on-line transaction processing applications in the same network

transmission frames to more completely fill the network transmission frames, which includes the

host processor delaying transmission of some of the I/O request data packets by a certain time

interval so that at least some of the network transmission frames each contain multiple I/O

request data packets, and transmitting each I/O request data packet in a frame no later than the

certain time interval after said each I/O request data packet is produced by one of the on-line

transaction processing applications,

wherein the network transmission frames include a first set of frames in which each

frame in the first set of frames is transmitted upon filling said each frame in the first set of

frames with data from one or more of the I/O request data packets so that said each frame in the

first set of frames cannot contain an additional I/O request data packet; and

the network transmission frames include a second set of frames in which each frame in

the second set of frames is transmitted upon delaying packet transmission for the certain time

interval, and said each frame in the second set of frames is not filled with data from one or more

of the I/O request data packets so that said each frame in the second set of frames cannot contain

an additional I/O request data packet.

14. (Original) The method as claimed in claim 13, which includes the host processor

dynamically adjusting the certain time interval in response to loading on the data network, the

certain time interval being increased for increased loading on the data network.

15. (Currently amended) The method as claimed in claim [[12]] 13, which includes the host

processor executing a periodic timer interrupt routine to insure that each I/O request data packet

is transmitted in a frame no later than a certain time interval after said each I/O request data

packet is produced by one of the on-line transaction processing applications.

16. (Currently amended) The method as claimed in claim [[12]] 13, wherein the I/O request

data packets include read I/O request data packets and write I/O request data packets, and the

method includes separately joining the read I/O request data packets together for transmission to

the network block storage, and separately joining the write I/O request data packets together for transmission to the network block storage.

17. (Original) The method as claimed in claim 16, which includes moving some of the read

I/O request data packets in front of some of the write I/O request data packets in some of the

frames.

18. (Currently amended) The method as claimed in claim [[12]] 13, which includes turning

on and off the joining of the I/O request data packets.

19. (Currently amended) The method as claimed in claim [[12]] 13, wherein the joining of

the I/O request data packets is turned off during a bulk transfer of database data.

20. (Currently amended) The method as claimed in claim [[12]] 13, which includes the host

processor executing an I/O request bunching routine that intercepts I/O request data packets sent

from the on-line transaction processing applications to a network block storage interface.

21. (Currently amended) The method of claim [[12]] 13, which includes storing the I/O

request data packets in a range of addresses of memory, preallocating a certain number of frames

in another region of memory, and joining the data packets during transfer of the data packets

from the range of addresses in memory to the preallocated frames in memory.

Ser. No. 10/761,767

Amendment in Reply to OA of 03/03/2009

22. (Original) The method of claim 21, which includes periodically updating the certain

number of preallocated frames.

23. (Currently amended) The method as claimed in claim [[12]] 13, which includes the

network attached storage bunching I/O replies into frames for transmission from the network

attached storage over the data network to the host processor.

(Canceled).

25. (Currently amended) The method as claimed in claim 24, A method of solving a

performance problem in a host processor programmed for executing on-line transaction

processing applications and having a network block storage interface for accessing network

attached storage coupled to the host processor via a data network, the performance problem

being caused by network transmission frames being only partially filled with I/O request data

packets from the on-line transaction processing applications, the performance problem being

solved by re-programming the host processor to join the I/O request data packets from different

ones of the on-line transaction processing applications in the same network transmission frames

to more completely fill the network transmission frames, which includes re-programming the

host processor to delay transmission of some of the I/O request data packets by a certain time

interval so that at least some of the network transmission frames each contain multiple I/O

request data packets, and to transmit each I/O request data packet in a frame no later than the

certain time interval after said each I/O request data packet is produced by one of the on-line

transaction processing applications,

wherein the network transmission frames include a first set of frames in which each

frame in the first set of frames is transmitted upon filling said each frame in the first set of

frames with data from one or more of the I/O request data packets so that said each frame in the

first set of frames cannot contain an additional I/O request data packet; and

the network transmission frames include a second set of frames in which each frame in

the second set of frames is transmitted upon delaying packet transmission for the certain time

interval, and said each frame in the second set of frames is not filled with data from one or more

of the I/O request data packets so that said each frame in the second set of frames cannot contain

an additional I/O request data packet.

26. (Original) The method as claimed in claim 25, which includes re-programming the host

processor for dynamic adjustment of the certain time interval in response to loading on the data

network, the certain time interval being increased for increased loading on the data network.

27. (Currently amended) The method as claimed in claim [[24]] 25, wherein the re-

programming of the host processor includes adding a periodic timer interrupt routine to insure

that each I/O request data packet is transmitted in a frame no later than a certain time interval

after said each I/O request data packet is produced by one of the on-line transaction processing

applications.

28. (Currently amended) The method as claimed in claim [[24]] 25, wherein the I/O request

data packets include read I/O request data packets and write I/O request data packets, and the

host processor is re-programmed for separately joining the read I/O request data packets together

for transmission to the network block storage, and separately joining the write I/O request data

packets together for transmission to the network block storage.

29. (Original) The method as claimed in claim 28, wherein the host processor is

reprogrammed to move some of the read I/O request data packets in front of some of the write

I/O request data packets in some of the frames.

30. (Currently amended) The method as claimed in claim [[24]] 25, which includes re-

programming the host processor for turning on and off the joining of the I/O request data

packets.

31. (Currently amended) The method as claimed in claim [[24]] 25, wherein the host

processor is re-programmed by adding an I/O request bunching module that intercepts I/O

request data packets sent from the on-line transaction processing applications to a network block

storage interface.

32. (Currently amended) The method as claimed in claim [[24]] 25, wherein the host

processor is re-programmed by modifying programming in the network block storage interface

that packs the frames with the I/O request data packets.

Amendment in Reply to OA of 03/03/2009

33. (Currently amended) The method as claimed in claim [[24]] 25, which includes re-

programming the network attached storage to bunch I/O replies into frames for transmission

from the network attached storage over the data network to the host processor.

(Canceled).

35. (Currently amended) The host processor as claimed in claim 34. A host processor

programmed for executing on-line transaction processing applications and having a network

block storage interface for accessing network attached storage coupled to the host processor via a

data network, the host processor being programmed for joining the I/O request data packets from

different ones of the on-line transaction processing applications into the same network

transmission frames to more completely fill the network transmission frames, wherein the host

processor is programmed for_delaying transmission of some of the I/O request data packets by a

certain time interval so that at least some of the network transmission frames each contain

multiple I/O request data packets, and transmitting each I/O request data packet in a frame no

later than the certain time interval after said each I/O request data packet is produced by one of

the on-line transaction processing applications, and

wherein the host processor is programmed to transmit each network transmission frame

upon the earlier of either filling said each network transmission frame with data from one or

 $\underline{\text{more of the I/O request data packets so that said each network transmission frame cannot contain}}$

an additional I/O request data packet, or delaying packet transmission for the certain time

Amendment in Reply to OA of 03/03/2009

interval, so that the network transmission frames include a first set of frames in which each

frame in the first set of frames is transmitted upon filling said each frame in the first set of

frames with data from one or more of the I/O request data packets so that said each frame in the

first set of frames cannot contain an additional I/O request data packet, and a second set of

frames in which each frame in the second set of frames is transmitted upon delaying packet

transmission for the certain time interval, and said each frame in the second set of frames is not

filled with data from one or more of the I/O request data packets so that said each frame in the

second set of frames cannot contain an additional I/O request data packet.

36. (Original) The host processor as claimed in claim 35, wherein the host processor is

programmed for dynamically adjusting the certain time interval in response to loading on the

data network, the certain time interval being increased for increased loading on the data network.

37. (Currently amended) The host processor as claimed in claim [[34]] 35, wherein the host

processor is programmed with a periodic timer interrupt routine to insure that each I/O request

data packet is transmitted in a frame no later than a certain time interval after said each I/O

request data packet is produced by one of the on-line transaction processing applications.

38. (Currently amended) The host processor as claimed in claim [[34]] 35, wherein the I/O

request data packets include read I/O request data packets and write I/O request data packets, and

the host processor is programmed for separately joining the read I/O request data packets

together for transmission to the network block storage, and for separately joining the write I/O

request data packets together for transmission to the network block storage.

39. (Original) The host processor as claimed in claim 38, which is programmed for moving

some of the read I/O request data packets in front of some of the write I/O request data packets in

some of the frames.

40. (Currently amended) The host processor as claimed in claim [[34]] 35, wherein the host

processor is programmed for turning on and off the joining of the I/O request data packets.

41. (Currently amended) The host processor as claimed in claim [[34]] 35, wherein the host

processor is programmed with an I/O request bunching routine that intercepts I/O request data

packets sent from the on-line transaction processing applications to the network block storage

interface.

42. (Currently amended) The host processor as claimed in claim [[34]] 35, wherein the host

processor is programmed for storing the I/O request data packets in a range of addresses of

memory, preallocating a certain number of frames in another region of memory, and joining the

data packets during transfer of the data packets from the range of addresses in memory to the

preallocated frames in memory.

Ser. No. 10/761,767 Amendment in Reply to OA of 03/03/2009

43. (Original) The host processor as claimed in claim 42, which is programmed for periodically updating the certain number of preallocated frames.
